The mechanisms by which oligodendroglia modulate CNS angiogenesis remain elusive. Previous in vitro data suggest that oligodendroglia regulate CNS endothelial cell proliferation and blood vessel formation through hypoxia inducible factor alpha (HIF α)-activated Wnt (but not VEGF) signaling. Using in vivo genetic models, we show that HIF α in oligodendroglia is necessary and sufficient for angiogenesis independent of CNS regions. At the molecular level, HIF α stabilization in oligodendroglia does not perturb Wnt signaling but rather activates VEGF. At the functional level, genetically blocking oligodendroglia-derived VEGF but not Wnt significantly decreases oligodendroglial HIF α -regulated CNS angiogenesis. Blocking astroglia-derived Wnt signaling reduces astroglial HIF α -regulated CNS angiogenesis. Together, our in vivo data demonstrate that oligodendroglial HIF α regulates CNS angiogenesis through Wnt-independent and VEGF-dependent signaling. These findings suggest an alternative mechanistic understanding of CNS angiogenesis by postnatal glial cells and unveil a glial cell type-dependent HIF α -Wnt axis in regulating CNS vessel formation.

The vasculature of the central nervous system (CNS), which is developed exclusively through angiogenesis, plays a crucial role in providing neural cells with nutrients and oxygen. CNS angiogenesis, the growth of new blood vessels from pre-existing ones, starts during embryonic development and matures during postnatal development in human and rodent brains, for example, by the age of one month in rodents¹. Dysregulated CNS angiogenesis negatively impacts postnatal brain development and functional recovery from brain injuries^{2–4}. The current study aimed to dissect the molecular regulation of postnatal CNS angiogenesis using *in vivo* genetic animal models.

The developing CNS parenchyma is exposed to physiological hypoxia with local oxygen concentration ranging from 0.5 to 7%⁵. Hypoxia-inducible factor α (HIF α) is a critical regulator that adapts neural cells to hypoxic conditions. The transcription factor HIF α , including HIF1 α and HIF2 α , is subjected to constant degradation. Von Hippel-Lindau (VHL), a negative regulator of HIF α 's transcriptional activity, plays an essential role in HIF α degradation. Under low oxygen or upon VHL disruption, HIF1 α and HIF2 α degradation is impaired and subsequently translocate into the nuclei where they regulate downstream target genes through forming transcriptional active complexes with the constitutive HIF1 β ^{6,7}. Previous data suggest that HIF α function in neural precursor cells is required for embryonic brain vascular development⁸. Recent data including those from our own laboratory show that HIF α function in oligodendroglial lineage cells may play a pivotal role in regulating postnatal angiogenesis in the brain white matter⁹ and in the spinal cord¹⁰. However, the molecular mechanisms underlying oligodendroglial HIF α -regulated angiogenesis are still controversial and remain incompletely defined.

The current concept stated that oligodendroglial HIF α promotes CNS angiogenesis through activating signaling pathway of Wnt but not vascular endothelial growth factor (VEGF)⁹. However, this “Wnt-dependent” view was supported only by *in vitro* studies and pharmacological manipulations⁹, in which “pathological” activation of Wnt signaling, poor cell-type selectivity and/or off-target effects of small compounds cannot be excluded. In this study, we present *in vivo* evidence supporting an alternative view in our mechanistic understanding of oligodendroglial HIF α -regulated CNS angiogenesis. Our *in vivo* genetic knockout data reveal that oligodendroglial HIF α regulates endothelial cell proliferation and angiogenesis in a VEGF-dependent but Wnt-independent manner and this regulation is independent of CNS regions during postnatal development. This data also demonstrate that postnatal astroglia regulate CNS angiogenesis at least in part through HIF α -activated Wnt signaling, unveiling a glial cell type-specific HIF α -Wnt connection in the CNS.

Results

Oligodendroglial HIF α regulates CNS angiogenesis. Endothelial cell (EC) proliferation is an essential step of angiogenesis and the blood vessel density is an end-point reflection of angiogenesis. Therefore, we used EC proliferation and vessel density as *in vivo* readouts of angiogenesis⁹. To quantify blood vessel density, we used the basement membrane marker Laminin to label blood vessels and employed a semi-automated approach to calculate the percentage of Laminin-occupying area among total assessed area (Supplementary Fig. 1). To determine whether oligodendroglial HIF α is required for angiogenesis throughout the postnatal CNS, *Cre-LoxP* approach was used to genetically ablate or stabilize HIF α and EC proliferation and vessel density were analyzed in the brain and the spinal cord.

We used *Cnp-Cre* line¹¹ to generate *Cnp-Cre:Hif1 α ^{fl/fl}* (HIF1 α conditional knockout, cKO), *Cnp-Cre:Hif2 α ^{fl/fl}* (HIF2 α cKO),

and *Cnp-Cre:Hif1 α ^{fl/fl}:Hif2 α ^{fl/fl}* (HIF1 α /HIF2 α or HIF α double cKO) mutants (Supplementary Fig. 2). Mice carrying *Cnp-Cre* transgene alone did not display any developmental abnormalities compared with non-*Cre* animals as previously reported¹¹ and supported by our assessment of CNS angiogenesis at postnatal 10 and motor function at postnatal one month (Supplementary Fig. 3). HIF1 α cKO or HIF2 α cKO did not influence blood vessel density, indicating a compensatory effect of oligodendroglial HIF1 α and HIF2 α on angiogenesis. In contrast, HIF1 α /HIF2 α double cKO (refer to as HIF α cKO hereafter) significantly impaired CNS angiogenesis evidenced by reduced blood vessel density (Fig. 1a–c) and diminished EC proliferation not only in the cerebral cortex but also in the spinal cord at postnatal 14 (Fig. 1d–g), suggesting that oligodendroglial HIF α is necessary for CNS angiogenesis.

The HIF α protein is constantly translated but subjected to rapid turnover via proteasome-mediated degradation, a process in which Von Hippel-Lindau product (VHL) is essential for HIF α degradation. Therefore, we employed *Cnp-Cre:Vhl^{fl/fl}* transgenic mice to genetically ablate VHL and stabilize HIF α function in oligodendroglial lineage cells (Supplementary Fig. 4). We found that the density of blood vessels and the proliferation of ECs were significantly increased in the cerebral cortex and spinal cord of *Cnp-Cre:Vhl^{fl/fl}* mice compared with those of non-*Cre* control mice at different time points in the early postnatal CNS (Fig. 1h–j). Stabilizing HIF α in oligodendroglial lineage cells did not have a major effect on the integrity of the blood-brain (spinal cord) barrier in the adult *Cnp-Cre:Vhl^{fl/fl}* mice (Supplementary Fig. 5).

Previous studies have reported that *Cnp-Cre* primarily targets oligodendroglial lineage cells and also a subpopulation of early neural progenitor cells^{12,13}. To corroborate the conclusion derived from *Cnp-Cre* transgenic mice, we assessed CNS angiogenesis in a different animal strain *Sox10-Cre:Vhl^{fl/fl}* in which *Sox10-Cre* mediated HIF α stabilization in the earlier stages of oligodendrocyte development in the CNS. Consistently, CNS angiogenesis was significantly increased in *Sox10-Cre:Vhl^{fl/fl}* mutants, as assessed by elevated blood vessel density (Fig. 1k), EC-specific *Pecam1* mRNA expression (Fig. 1l), and EC densities (Fig. 1m). Taken together, our loss (gain)-of-function results suggest that oligodendroglial HIF α is necessary and sufficient for angiogenesis and that the angiogenic regulation by oligodendroglial HIF α is independent of CNS regions.

Oligodendroglial HIF α does not regulate Wnt signaling. To determine whether HIF α in oligodendroglial lineage cells regulates Wnt/ β -catenin signaling, we quantified the Wnt/ β -catenin target gene *Axin2*, *Naked1*, and *Notum*, which are reliable readouts for the signaling activation¹⁰. We found no significant changes in the mRNA levels of those genes in HIF α -stabilized spinal cord and forebrain of *Cnp-Cre:Vhl^{fl/fl}* mutants at different time points (Fig. 2a) compared with those of non-*Cre* controls. Consistently, western blot assay showed that the active form of β -catenin (dephosphorylated on Ser37 or Thr41) and *Axin2* did not change (Fig. 2b), indicating that stabilizing oligodendroglial HIF α does not perturb the activity of Wnt/ β -catenin signaling in the CNS. Furthermore, we found no significant change in the mRNA level of Wnt7a in the CNS of *Cnp-Cre:Vhl^{fl/fl}* mice compared with non-*Cre* controls (Fig. 2c). We crossed Wnt reporter transgenic mice BAT-lacZ¹⁴ with *Cnp-Cre:Vhl^{fl/fl}* mutants and found no difference in lacZ mRNA level in the spinal cord of BAT-lacZ/*Cnp-Cre:Vhl^{fl/fl}* mice compared with age-matched BAT-lacZ mice (Fig. 2d).

We further assessed the activity of Wnt/ β -catenin signaling in a different animal strain of *Sox10-Cre:Vhl^{fl/fl}* mice. Consistent with

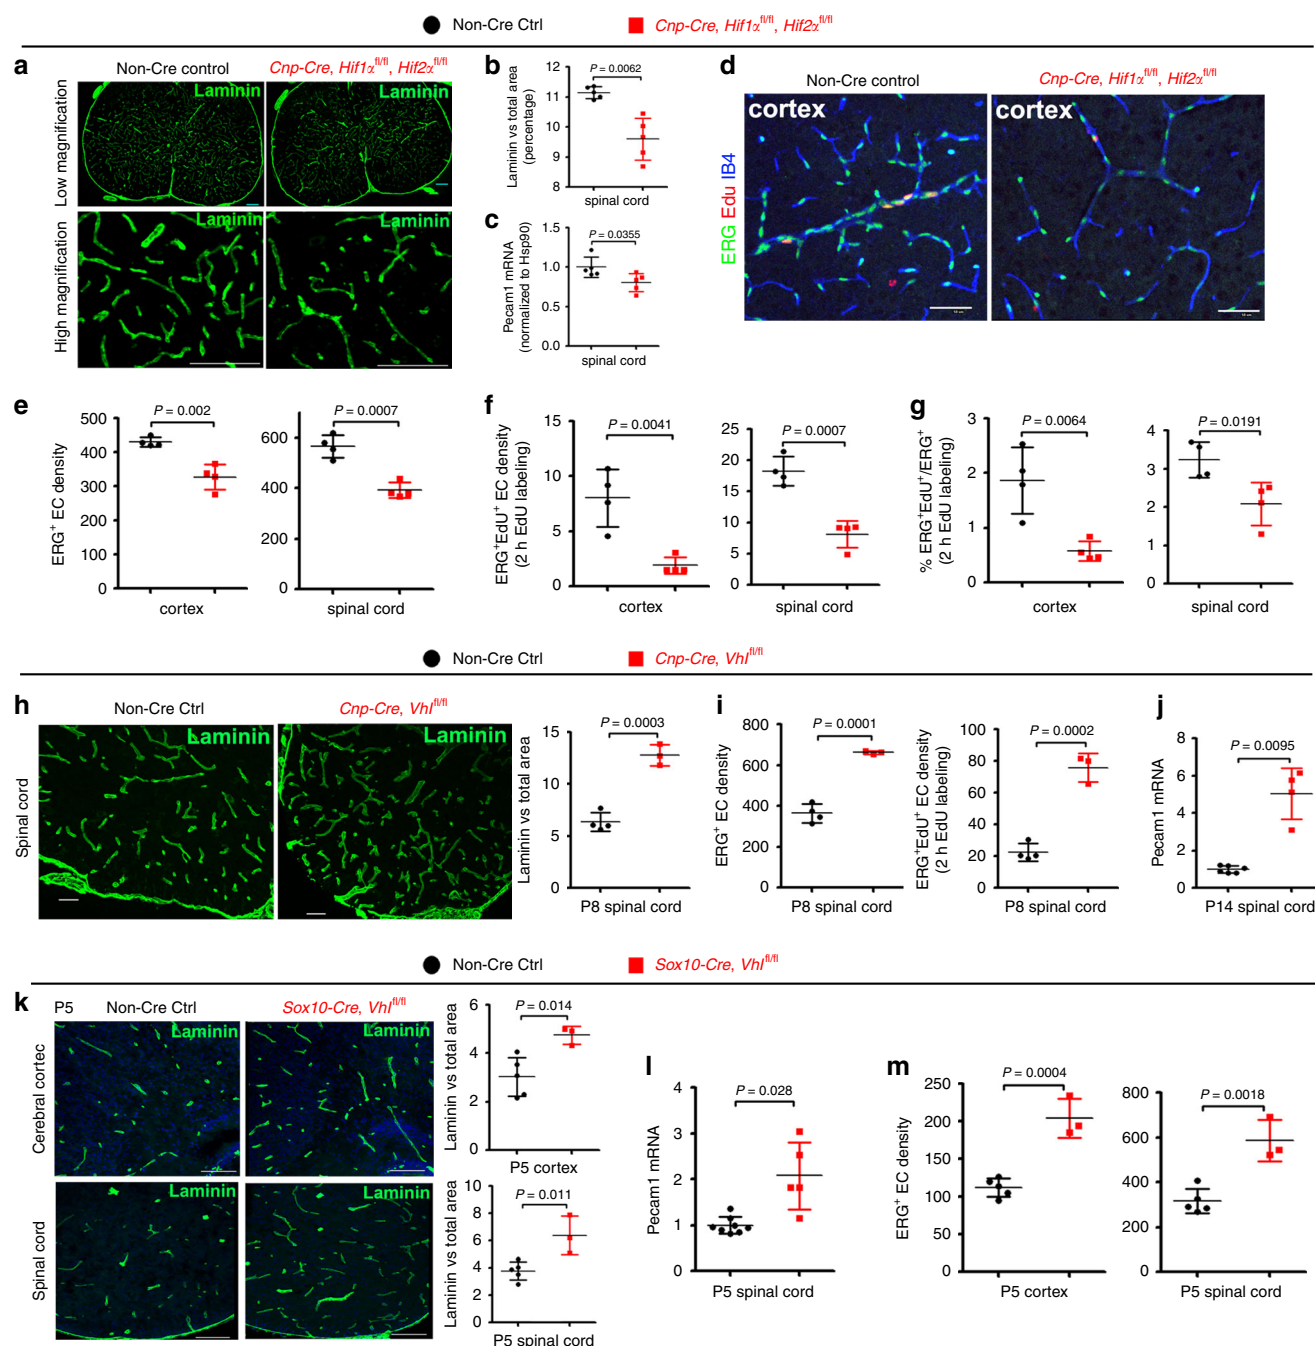

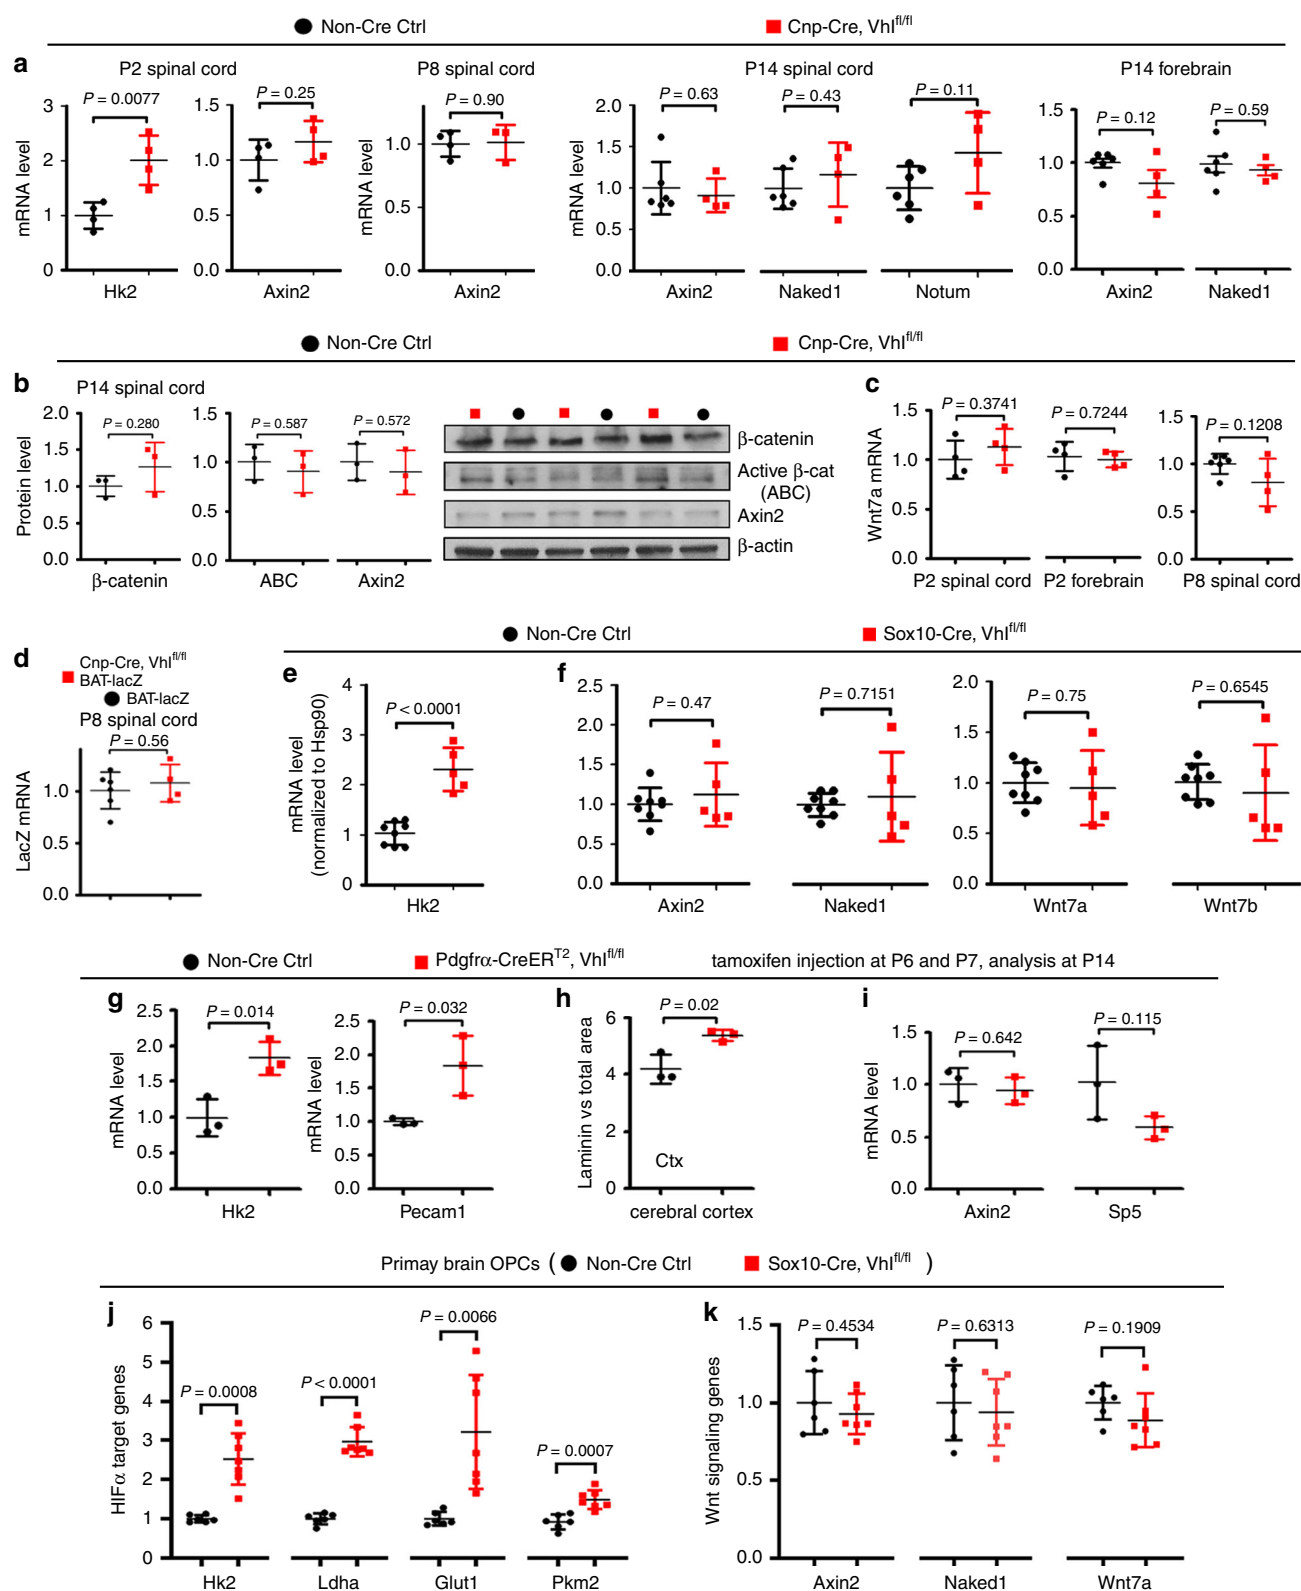

Fig. 1 CNS region-independent regulation of angiogenesis by oligodendroglial HIF α . **a** Representative images of blood vessels labeled by the basement membrane marker Laminin in the spinal cord of *Cnp-Cre;Hif1 $\alpha^{fl/fl}$;Hif2 $\alpha^{fl/fl}$* and non-Cre littermate controls at postnatal day 14 (P14). Scale bars = 100 μ m. **b** Percentage of Laminin⁺ area among total assessed area. Two-tailed Student's *t* test with Welch's correction, $t_{(4,618)} = 4.767$, $n = 5$ each group. **c** RT-qPCR assay of *Pecam1* mRNA (a.k.a. CD31), a marker of endothelial cells (ECs), in the P14 spinal cord. Two-tailed Student's *t* test, $t_{(8)} = 2.526$, $n = 5$ each group. **d-f** Representative images of immunohistochemical staining of ERG (a nuclear marker of ECs), isolectin B4 (IB4, labeling blood vessel basement membrane), and EdU (labeling actively dividing cells) and densities of marker positive cells (# per mm²) in *Cnp-Cre, Hif1 $\alpha^{fl/fl}$, Hif2 $\alpha^{fl/fl}$* and littermate control mice at P14. Two hours EdU pulse labeling. Two-tailed Student's *t* test, ERG⁺, $t_{(6)} = 5.200$ cortex, $t_{(6)} = 6.358$ spinal cord; ERG⁺EdU⁺, $t_{(6)} = 4.496$ cortex, $t_{(6)} = 6.365$ spinal cord. $n = 4$ each group. **g** Percentage of ERG⁺ ECs that are EdU⁺. Two-tailed Student's *t* test, $t_{(6)} = 4.089$ cortex, $t_{(6)} = 3.181$ spinal cord. $n = 4$ each group. **h** Representative images and quantification of Laminin in the spinal cord of P8 *Cnp-Cre, Vhl $^{fl/fl}$* , and non-Cre control mice. Two-tailed Student's *t* test, $t_{(5)} = 8.831$. $n = 4$ Ctrl, 3 VHL cKO. **i** Densities (per mm²) of ERG⁺ ECs and ERG⁺EdU⁺ proliferating ECs in the P8 spinal cord. Two-tailed Student's *t* test, $t_{(5)} = 11.10$ ERG⁺, $t_{(5)} = 9.981$ ERG⁺EdU⁺. $n = 4$ Ctrl, 3 VHL cKO. **j** RT-qPCR of *Pecam1* mRNA in P14 spinal cord. Two-tailed Student's *t* test with Welch's correction, $t_{(3,081)} = 5.941$. $n = 6$ Ctrl, 4 VHL cKO. **k** Representative images and quantification of Laminin in P5 *Sox10-Cre, Vhl $^{fl/fl}$* and non-Cre controls. Two-tailed Student's *t* test, $t_{(6)} = 3.625$ spinal cord, $t_{(6)} = 3.428$ cortex. $n = 5$ Ctrl, 3 VHL cKO. **l** RT-qPCR of *Pecam1* mRNA in P5 spinal cord. Two-tailed Student's *t* test with Welch's correction, $t_{(4,309)} = 3.257$. $n = 8$ Ctrl, 5 VHL cKO. **m** Densities (per mm²) of ERG⁺ ECs at P5. Two-tailed Student's *t* test, $t_{(6)} = 6.964$ cortex, $t_{(6)} = 5.324$ spinal cord. $n = 5$ Ctrl, 3 VHL cKO. Scale bar: **a, k** 100 μ m; **d, h** 50 μ m. Data are shown as mean \pm s.d. Source data of **b, c, e, m** are provided as a Source Data file.

Cnp-Cre;Vhl^{fl/fl} mice, HIFα was stabilized in the CNS of *Sox10-Cre;Vhl^{fl/fl}* mutants, as shown by the elevated expression of HIFα target gene *Hk2* (Fig. 2e). However, Wnt/β-catenin signaling was not perturbed, as evidenced by similar activity of Wnt/β-catenin signaling assessed at the mRNA (Fig. 2f) and protein (Supplementary Fig. 6) levels. The unperturbed activity of Wnt/β-catenin signaling was further corroborated by evidence from a time-

conditional *Pdgfra-CreER^{T2};Vhl^{fl/fl}* strain in which *Pdgfra-CreER^{T2}* elicited a greater than 85% of recombination efficiency and specificity in early postnatal oligodendrocyte progenitor cells (OPCs) (Supplementary Fig. 7). Tamoxifen-induced VHL ablation in OPCs resulted in HIFα stabilization and elevated angiogenesis, as demonstrated by significant increase in the expression of HIFα target gene *Hk2* and EC-specific *Pecam1*

Fig. 2 Oligodendroglial HIF α does not activate Wnt/ β -catenin signaling. **a** RT-qPCR assay of mRNA levels of HIF α target gene *Hk2* and Wnt/ β -catenin target genes *Axin2*, *Naked1*, and *Notum*. Two-tailed Student's *t* test, $t_{(6)} = 3.936$ *Hk2*, $t_{(6)} = 1.275$ *Axin2* at P2; $t_{(5)} = 0.1307$ *Axin2* at P8; $t_{(8)} = 0.4906$ *Axin2*, $t_{(8)} = 0.8386$ *Naked1*, $t_{(8)} = 1.821$ *Notum* at P14 spinal cord; $t_{(8)} = 1.736$ *Axin2*, $t_{(8)} = 0.5617$ *Naked1* at P14 forebrain. $n = 6$ Ctrl, 4 VHL cKO. **b** Western blot assay of total β -catenin, active β -catenin, and *Axin2*. (Fig. 2g) and the density of cerebral blood vessels (Fig. 2h). However, the mRNA expression of Wnt target genes *Axin2* and *Sp5* (Fig. 2i) and the protein levels of active β -catenin and *Naked1* (Supplementary Fig. 8) were indistinguishable between *Pdgfra-CreER^{T2}:Vhl^{fl/fl}* mutants and non-Cre controls, indicating that Wnt/ β -catenin signaling activity was not altered by oligodendroglial HIF α stabilization.

Previous study reported an autocrine activation of Wnt/ β -catenin signaling in OPCs by HIF α stabilization⁹. To assess the autocrine activity of Wnt/ β -catenin signaling, we treated purified primary OPCs with HIF α stabilizer DMOG⁹ in the presence or absence of HIF α signaling blocker Chetomin¹⁵ (Supplementary Fig. 9a). Our results showed that pharmacological stabilizing HIF α activated HIF α signaling target genes (Supplementary Fig. 9b) but did not activate Wnt/ β -catenin target genes nor *Wnt7a* and *Wnt7b* (Supplementary Fig. 9c) in primary OPCs isolated from neonatal brain. We also quantified the activity of Wnt/ β -catenin signaling in primary OPCs which were isolated from neonatal *Sox10-Cre:Vhl^{fl/fl}* brain. Consistent with the in vivo data (Fig. 2e), HIF α target genes were significantly increased in primary VHL-deficient OPCs (Fig. 2j). However, neither Wnt/ β -catenin target genes *Axin2* and *Naked1* nor *Wnt7a* were increased in primary VHL-deficient OPCs (Fig. 2k), suggesting that stabilizing oligodendroglial HIF α does not perturb Wnt/ β -catenin signaling in primary OPCs.

To determine whether HIF α deletion affects Wnt/ β -catenin signaling, we analyzed Wnt/ β -catenin activity in the early postnatal CNS of *Cnp-Cre:HIF α cKO* and *Pdgfra-CreER^{T2}:HIF α cKO* mutants. Consistent with HIF α -stabilized mutants (Fig. 2), we found no evidence of Wnt/ β -catenin signaling perturbation in both strains of HIF α cKO mutants (Supplementary Fig. 10). Collectively, our in vivo and in vitro data demonstrate that Wnt/ β -catenin signaling is unlikely a downstream target of oligodendroglial HIF α as previously reported⁹ and suggest that oligodendroglial HIF α may regulate CNS angiogenesis independent of Wnt/ β -catenin signaling.

OPC autocrine Wnt signaling is dispensable for angiogenesis.

WLS is an essential factor of Wnt secretion from Wnt-producing cells and its deficiency blocks Wnt ligands from activating the downstream pathways in Wnt-receiving cells^{16–19}. To determine whether WLS deficiency affects Wnt secretion from oligodendroglial lineage cells, we knocked down WLS in primary *Wnt7a*-expressing OPCs and assessed Wnt secretion and autocrine Wnt/ β -catenin activity (Fig. 3a, b). Because *Wnt7a* has been shown as one of the major Wnt ligand genes expressed in OPCs at the mRNA level^{9,20}, we overexpressed *Wnt7a* in primary OPCs.

Our enzyme-linked immunosorbent assay (ELISA) of the culture medium showed that WLS knockdown significantly reduced *Wnt7a* concentration secreted from *Wnt7a*-expressing OPCs (Fig. 3c). Autocrine Wnt/ β -catenin signaling was activated in *Wnt7a*-expressing OPCs, as evidenced by the increased expression of Wnt target genes *Axin2* and *Sp5* (Fig. 3d), but this activation was blocked in WLS-deficient OPCs (Fig. 3d). Our data suggest that WLS is required for Wnt secretion from OPCs.

To define the putative in vivo role of Wnt signaling in HIF α -regulated CNS angiogenesis, we generated VHL/WLS double mutant hybrids to block Wnt secretion from HIF α -stabilized oligodendroglial lineage cells (Fig. 4a). Because constitutive *Sox10-Cre:Vhl^{fl/fl}* pups died at very early postnatal ages, we used an inducible Cre line *Sox10-CreER^{T2}* to stabilize HIF α and disrupt WLS (Fig. 4b, c) in *Sox10⁺* oligodendroglial lineage cells (OPCs and differentiated oligodendroglia). Our fate-mapping data showed that *Sox10-CreER^{T2}* elicited ~60% of recombination efficiency and greater than 90% of oligodendroglial specificity in *Sox10⁺* oligodendroglial lineage cells in the early postnatal CNS (Supplementary Fig. 11). We confirmed that HIF α 's function was indeed stabilized in the spinal cord of *Sox10-CreER^{T2}:Vhl^{fl/fl}* (HIF α -stabilized mice) and *Sox10-CreER^{T2}:Vhl^{fl/fl};Wls^{fl/fl}* (HIF α -stabilized/WLS-disrupted mice), as evidenced by the elevated expression of HIF α target gene *Hk2* (Fig. 4d) and *Ldha* (Fig. 4e) in comparison with non-Cre controls. Our analysis demonstrated that blocking Wnt secretion by disrupting WLS did not alter HIF α stabilization-elicited CNS angiogenesis in HIF α -stabilized/WLS-disrupted mice compared with HIF α -stabilized mice, which was supported by unchanged levels of endothelial *Pecam1* mRNA expression (Fig. 4f) and unchanged densities of blood vessels (Fig. 4g–j), ERG⁺ ECs (Fig. 4k), and ERG⁺EdU⁺ dividing ECs (Fig. 4l) in the spinal cord and cerebral cortex of HIF α -stabilized/WLS-disrupted mice compared with those of HIF α -stabilized mice. These data suggest that oligodendroglial lineage-derived Wnt signaling plays a minor role in HIF α -regulated angiogenesis in the early postnatal CNS.

Next, we used a different Cre transgenic line *Pdgfra-CreER^{T2}* to stabilize HIF α specifically in OPCs. OPC-specific HIF α stabilization enhanced blood vessel density (Fig. 5a–d) and increased the number of ERG⁺ ECs (Fig. 5e, f) in the spinal cord and cerebral cortex of *Pdgfra-CreER^{T2}:Vhl^{fl/fl}* animals compared with those in non-Cre controls. However, blocking Wnt secretion from OPCs by disrupting WLS did not affect blood vessel formation and endothelial cell density in the CNS of HIF α stabilized/WLS-disrupted mice compared with HIF α stabilized mice (*Pdgfra-CreER^{T2}:Vhl^{fl/fl};Wls^{fl/fl}* versus *Pdgfra-CreER^{T2}:Vhl^{fl/fl}*) (Fig. 5c–f). The data from two independent Cre transgenic lines collectively

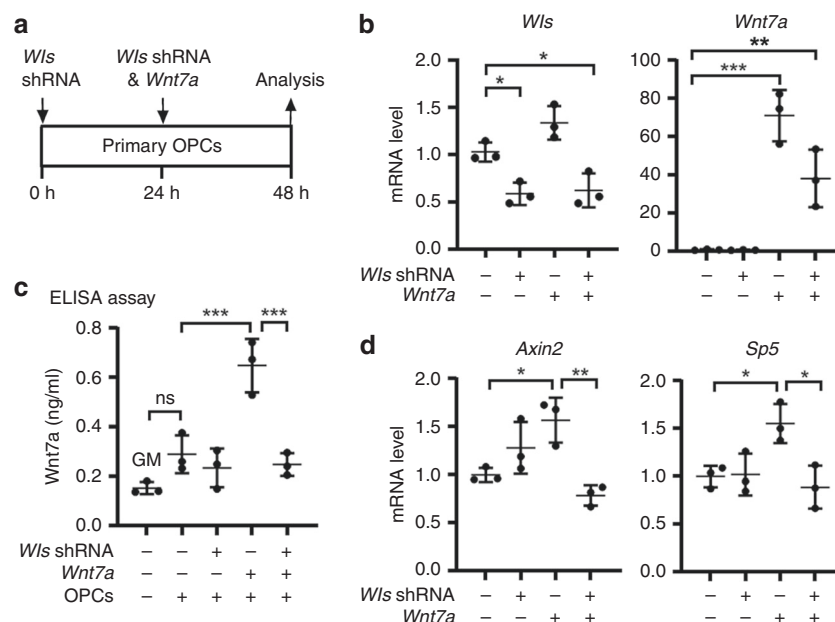

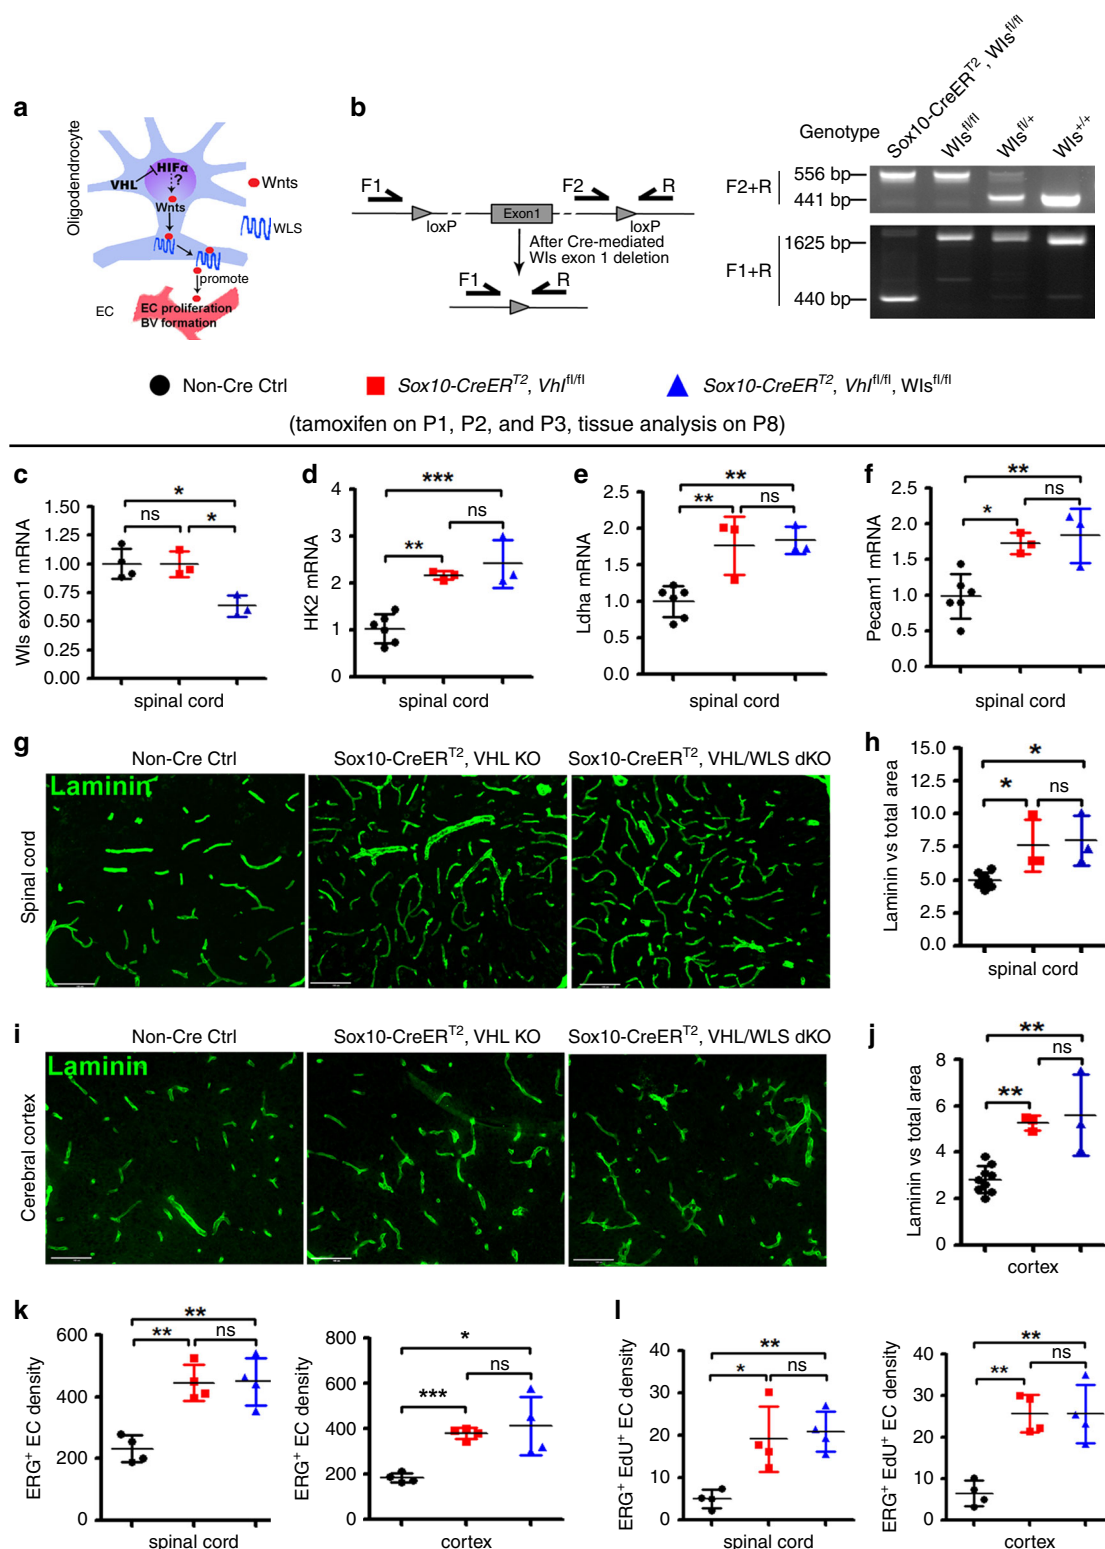

Fig. 3 WLS is required for Wnt secretion from OPCs. **a** brain primary OPCs growing in the growth medium (GM) were transfected with *Wls*-shRNA and *Wnt7a* plasmids, and OPC mRNA and culture medium were collected for analysis 48 hours (h) after the first *Wls*-shRNA transfection. **b** RT-qPCR assay of *Wls* and *Wnt7a* mRNA in transfected primary OPCs. One-way ANOVA followed by Tukey's multiple comparisons, * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$. $F_{(3,8)} = 17.41$, $P = 0.007$ *Wls*, $F_{(3,8)} = 33.82$, $P < 0.0001$ *Wnt7a*. $n = 3$ each group. **c** ELISA measurement of Wnt7a protein concentration in the GM in the absence and presence of OPCs in the dish with *Wls*-shRNA and *Wnt7a* transfection. Data are shown as mean \pm s.d. Source data of **b–d** are provided as a Source Data file.

suggest that oligodendroglia-derived Wnt signaling is dispensable for HIF α -regulated CNS angiogenesis in vivo.

Oligodendroglial HIF α activates VEGFA. A previous study reported that VEGFA was unperturbed by oligodendroglial HIF α stabilization⁹. We revisited the potential connection between HIF α and VEGFA in oligodendrocytes both in vivo and in vitro. HIF1 α cKO (or HIF2 α cKO) alone did not alter *Vegfa* mRNA level in the CNS of *Cnp-Cre:Hif1 α ^{fl/fl}* (or *Cnp-Cre:Hif2 α ^{fl/fl}*) mutants compared with non-Cre controls (data not shown), indicating a redundancy of oligodendroglial HIF1 α and HIF2 α in regulating VEGFA. HIF α double cKO (i.e., *Cnp-Cre:Hif1 α ^{fl/fl}; Hif2 α ^{fl/fl}*) decreased *Vegfa* mRNA expression in the spinal cord (Fig. 6a) and reduced the secretion of VEGFA from primary brain OPCs into the culture medium (Fig. 6b). Conversely, genetic HIF α stabilization by VHL deletion increased *Vegfa* mRNA expression in the spinal cord of *Cnp-Cre:Vhl^{fl/fl}* animals (Fig. 6c, d1–d4). Double fluorescent in situ hybridization confirmed that *Vegfa* mRNA was upregulated in *Plp* mRNA⁺ oligodendroglial lineage cells in vivo (Fig. 6e1–e2). Moreover, time-conditional and stage-specific VHL cKO demonstrated that genetic HIF α stabilization activated VEGFA not only in PDGFR α ⁺ OPCs (*Pdgfra-CreERT2:Vhl^{fl/fl}* strain) (Fig. 6f) but also in PLP⁺ oligodendroglia (*Plp-CreERT2:Vhl^{fl/fl}* strain) (Fig. 6g). Pharmacological DMOG treatment increased *Vegfa* mRNA expression and HIF α signaling blocker Chetomin prevented DMOG-induced *Vegfa* activation in primary OPCs purified from neonatal murine brains (Fig. 6h). Furthermore, *Vegfa* mRNA was elevated by greater than 3-fold in primary OPCs purified from neonatal *Sox10-Cre:Vhl^{fl/fl}* mice compared with those from non-Cre littermate controls (Fig. 6i). All these data suggest that VEGFA is regulated by HIF α in oligodendroglial lineage cells.

Oligodendroglial HIF α regulates angiogenesis through VEGFA. The regulation of VEGFA by oligodendroglial HIF α led us to hypothesize that VEGFA may be a crucial downstream molecule that couples oligodendroglial HIF α and CNS endothelial cell proliferation and vessel formation. To test this hypothesis, we generated *Pdgfra-CreERT2:Vhl^{fl/fl};Vegfa^{fl/fl}* (HIF α -stabilized/VEGFA-disrupted), *Pdgfra-CreERT2:Vhl^{fl/fl}* (HIF α -stabilized), and non-Cre control mice (Fig. 7a, b). The mRNA level of EC-specific marker PECAM1 was significantly attenuated in the spinal cord of *Pdgfra-CreERT2:Vhl^{fl/fl};Vegfa^{fl/fl}* mice compared with that of *Pdgfra-CreERT2:Vhl^{fl/fl}* mice (Fig. 7c). The densities of blood vessels (Fig. 7d, e), ERG⁺ total ECs (Fig. 7f), and ERG⁺BrdU⁺ proliferating ECs (Fig. 7g) were all significantly reduced in the spinal cord and cerebral cortex of *Pdgfra-CreERT2:Vhl^{fl/fl};Vegfa^{fl/fl}* mice compared with those of *Pdgfra-CreERT2:Vhl^{fl/fl}* mice. These data demonstrate that VEGFA disruption attenuates oligodendroglial HIF α -regulated CNS angiogenesis, thus providing unambiguous in vivo data arguing for an essential role of VEGFA in coupling oligodendroglial HIF α function and CNS angiogenesis.

Astroglial HIF α regulates CNS angiogenesis via Wnt signaling. Astroglial maturation is also temporally and functionally coupled with postnatal CNS angiogenesis. We assess the connection of astroglial HIF α and Wnt/ β -catenin activation in the CNS. We first used the mouse *Gfap* promoter-driven constitutive Cre, i.e. *mGfap-Cre* to genetically stabilize HIF α in astroglia. The efficiency of *mGfap-Cre*-mediated recombination among astroglial lineage cells, quantified by Cre-mediated EYFP reporter, was low (~35%) in the CNS in the early postnatal CNS by P10 (Supplementary Fig. 12a–c) and progressively increased during postnatal CNS development (Supplementary Fig. 12d–f). Our fate-mapping

data showed that EYFP reporter, which is an indicator of *mGfap-Cre* activity, was expressed in GFAP⁺ or S100 β ⁺ astrocytes, but not in Sox10⁺ oligodendroglial lineage cells, NeuN⁺ neurons (Fig. 8a), or ERG⁺ ECs (data not shown) in the spinal cord and the cerebral cortex of adult *mGfap-Cre:Rosa26-EYFP* mice at P60, confirming that *mGfap-Cre* primarily targets astroglial lineage cells in those CNS regions.

We observed a significant increase in the density of Laminin⁺ blood vessels (Fig. 8b, c) and in the mRNA expression of EC-specific

PECAM1 (Fig. 8d) throughout the CNS of *mGfap-Cre:Vhl^{fl/fl}* mutants compared with non-Cre control mice by P30 when Cre-mediated recombination efficiency was greater than 80% (Fig. 8a, Supplementary Fig. 12). Double immunohistochemistry showed that blood-borne macromolecule IgG was confined to Laminin⁺ blood vessels in *mGfap-Cre:Vhl^{fl/fl}* mice, a similar pattern to that in age-matched non-Cre controls (Fig. 8e, arrowheads), indicating that the function of the blood-brain (spinal cord) barrier does not appear compromised although the vessel density is elevated.

Fig. 4 Blocking Wnt secretion from oligodendroglial lineage cells does not affect HIF α -regulated CNS angiogenesis. **a** Schematic diagram depicting putative regulation between HIF α -Wnt axis in glio-vascular units. **b** Primer design (left) and PCR detection (right) of *Wls* gene deletion. Unexpectedly, we found that stabilizing HIF α in astroglial lineage cells (Fig. 8f) remarkably activated Wnt/ β -catenin signaling in the CNS of *mGfap-Cre:Vhl^{fl/fl}* mice, as shown by significant elevation in the expression of Wnt/ β -catenin signaling target genes *Axin2* and *Notum* in spinal cord and brain (Fig. 8g). Histological (Fig. 8h) and Western blot (cf Fig. 9a, b) assay demonstrated that the active form of β -catenin (dephosphorylated on Ser37 or Thr41) was significantly increased in *mGfap-Cre:Vhl^{fl/fl}* mice. Double immunohistochemistry confirmed the presence of elevated active β -catenin in PECAM1⁺ ECs (Fig. 8i, arrowheads). Collectively, our data suggest that stabilizing HIF α in astroglial lineage cells increases CNS angiogenesis and activates Wnt/ β -catenin signaling in ECs.

Wnt/ β -catenin signaling activation in ECs by astroglial HIF α stabilization led us to hypothesize that astroglia-derived Wnt signaling may instead play a major role in HIF α -regulated CNS angiogenesis. To test this hypothesis, we generated *mGfap-Cre:Vhl^{fl/fl};Wls^{fl/fl}* mice to stabilize HIF α 's function and simultaneously disrupting Wnt secretion from HIF α -stabilized astroglia. Our data showed that Wnt signaling activity was significantly reduced in the spinal cord of *mGfap-Cre:Vhl^{fl/fl};Wls^{fl/fl}* mice compared with that of *mGfap-Cre:Vhl^{fl/fl}* mice (Fig. 9a, b), thus verifying the efficacy of blocking astroglia-derived Wnt signaling in vivo by WLS deletion. Intriguingly, disrupting astroglia-derived Wnt signaling significantly reduced the densities of blood vessels (Fig. 9c–e) and ERG⁺ ECs (Fig. 9f–h) in the CNS of *mGfap-Cre:Vhl^{fl/fl};Wls^{fl/fl}* double mutant mice compared with *mGfap-Cre:Vhl^{fl/fl}* mice, indicating that astroglia-derived Wnt signaling is a downstream mediator of astroglial HIF α -regulated CNS angiogenesis.

Our results indicated that the constitutive *mGfap-Cre* elicited a poor recombination efficiency in early postnatal astrocytes (Supplementary Fig. 12). To determine whether early postnatal astrocytes regulate CNS angiogenesis through HIF α -activated Wnt signaling, we generated *Aldh1l1-CreER^{T2};Vhl^{fl/fl};Wls^{fl/fl}* mutants. Our data demonstrated a greater than 90% of recombination efficiency and 95% of astroglial specificity in the spinal cord and cerebral cortex of *Aldh1l1-CreER^{T2};Rosa26-EYFP* at P8 when tamoxifen was injected at P1, P2 and P3 (Supplementary Fig. 13). Consistent with the data derived from *mGfap-Cre:Vhl^{fl/fl};Wls^{fl/fl}* strain, we found that the densities of blood vessels and ECs were significantly increased in *Aldh1l1-CreER^{T2};Vhl^{fl/fl}* mutants compared with those in non-Cre controls and that simultaneous WLS ablation significantly reduced the densities of blood vessels and ECs in the cortex and spinal cord of *Aldh1l1-CreER^{T2};Vhl^{fl/fl};Wls^{fl/fl}* mutants

compared with those of *Aldh1l1-CreER^{T2};Vhl^{fl/fl}* animals at early postnatal age of P8 (Fig. 10). These data provide a strong genetic proof that HIF α -activated Wnt signaling is a major downstream pathway by which astroglia regulate angiogenesis during postnatal CNS development.

Discussion

The maturation of glial cells including oligodendroglia and astroglia in the developing human and murine brain is temporally and functionally coupled with the maturation of the CNS vascular network²¹. The regulation of CNS angiogenesis by glial cells is critical for postnatal CNS development and investigating the molecular underpinnings of CNS angiogenesis has clinical implications in neural repair after CNS damage in which hypoxia is commonly present^{4,21,22}. In this study, we employed a battery of genetic mutant mice and presented several significant findings: (1) oligodendroglial HIF α is necessary and sufficient for postnatal CNS angiogenesis and this regulation occurs in a manner independent of CNS regions; (2) in sharp contrast to the previous report⁹, HIF α stabilization in oligodendroglial lineage cells does not perturb Wnt/ β -catenin signaling, but remarkably activates VEGF, and genetically blocking oligodendroglia-derived VEGF but not Wnt reduces oligodendroglial HIF α -regulated CNS angiogenesis; (3) Wnt signaling is a downstream pathway by which astroglial HIF α regulates CNS angiogenesis. Our findings represent an alternative view in our mechanistic understanding of oligodendroglial HIF α -regulated angiogenesis from a Wnt-dependent/VEGF-independent view⁹ to a VEGF-dependent/Wnt-independent one, and also unveil a glial cell type-dependent HIF α -Wnt axis (oligodendroglial vs astroglia) in regulating CNS angiogenesis (Supplementary Fig. 14).

Previous data suggested that the regulation of Wnt/ β -catenin signaling (activation or repression) by HIF α is cell type and/or context-dependent^{10,23–27}. It is important to determine whether HIF α in CNS glial cells differentially regulates Wnt/ β -catenin signaling in vivo. A recent study reported that oligodendroglial HIF α could activate Wnt/ β -catenin signaling not only in oligodendroglial lineage cells but also in endothelial cells through HIF α -mediated Wnt7a/7b expression⁹. However, the in vivo and in vitro data presented in this study do not support this assertion. Here, we employed five different strains of oligodendroglial Cre (two constitutive Cre and three inducible Cre) to genetically stabilize HIF α and found no evidence of Wnt/ β -catenin activation or Wnt7a/7b upregulation in the brain and the spinal cord and in primary OPCs. The failure to detect Wnt/ β -catenin activation is unlikely due to the inefficiency of HIF α stabilization because the

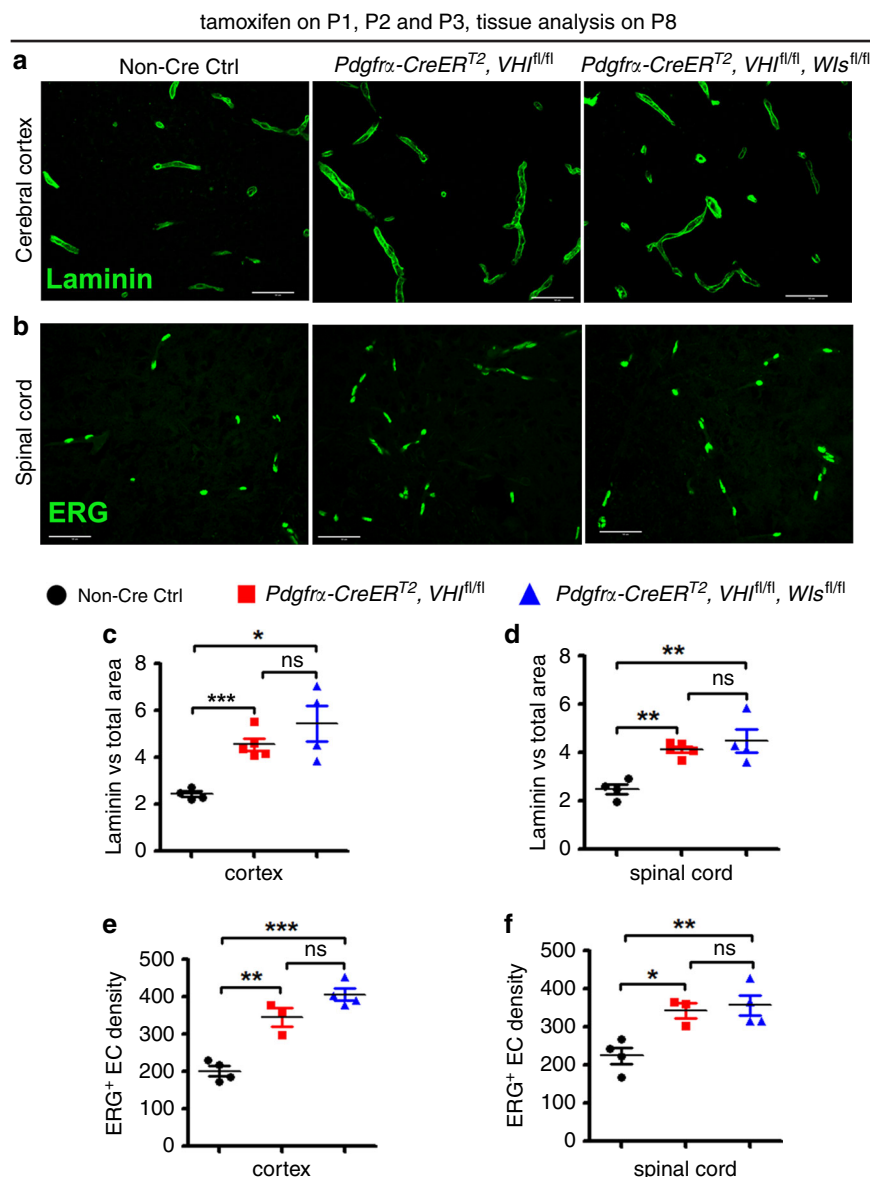

Fig. 5 Blocking Wnt secretion from oligodendrocyte progenitor cells (OPCs) does not affect HIF α -regulated CNS angiogenesis. **a, b** Representative confocal images of Laminin-labeled blood vessels and ERG-labeled ECs in each group of mice. canonical HIF α target genes, for example, those which are involved in glycolysis, are consistently and significantly upregulated in our transgenic animals and in primary OPCs, thus verifying the efficacy of HIF α stabilization. In sharp contrast, we found that Wnt/ β -catenin signaling activity is significantly upregulated in the CNS of astroglial HIF α -stabilized mice, suggesting that our experimental approach is effective in quantifying the changes of Wnt/ β -catenin activity and that the regulation of Wnt/ β -catenin signaling by HIF α is glial cell type-dependent in the CNS.

Inspired by glial cell type (oligodendroglia vs astroglia)-dependent activation of Wnt/ β -catenin signaling, we proposed a working model in which HIF α -activated Wnt signaling regulates endothelial cell proliferation and vessel formation in a

cell type-dependent manner (Supplementary Fig. 14). To avoid the intrinsic caveats of pharmacological compounds and in vitro culture systems, we employed in vivo genetic models of VHL/WLS double cKO to stabilize HIF α and simultaneously disrupt the secretion of Wnt ligands. Indeed, our data demonstrate that WLS-deficiency decreases Wnt secretion and Wnt7a-induced autocrine Wnt/ β -catenin signaling in primary OPCs and that disrupting WLS in astroglia reduces the activity of astroglial HIF α -regulated Wnt/ β -catenin signaling in the CNS. Based on VHL/WLS double cKO systems, we provide strong genetic evidence that HIF α -regulated Wnt signaling from astroglia but not oligodendroglia plays a crucial role in regulating postnatal CNS angiogenesis. Our findings argue against a major role oligodendroglia-derived/HIF α -activated

Wnt/ β -catenin signaling in angiogenesis in the developing murine CNS as previously reported⁹.

There are 19 Wnt ligands in rodents, which can be grossly classified into canonical and non-canonical sub-types depending on the necessity of β -catenin for the signaling activation¹⁰. WLS ablation blocks the secretion of all Wnt members from Wnt-producing cells^{16–19,28}. In our genetic models, we demonstrate that ablation of WLS remarkably reduces astroglial

HIF α -mediated canonical Wnt/ β -catenin signaling. However, we cannot exclude the possibility that astroglia-derived non-canonical Wnt signaling is also altered in our genetic manipulation which may be potentially involved in CNS angiogenic regulation²⁹. Moreover, it remains unclear which Wnt ligand(s) plays a major role in coupling astroglial HIF α with CNS angiogenesis. Our preliminary data do not support a major role of Wnt7a/7b, because neither Wnt7a nor Wnt7b expression was

activated in oligodendroglial and astroglial HIF α -stabilized CNS. Future studies are needed to pinpoint which Wnt ligand (s) are the downstream mediator(s) of astroglial HIF α -regulated CNS angiogenesis.

VEGF (i.e. VEGFA) is a well-established angiogenic and neurotrophic factor in the CNS^{4,30–35}. VEGFA regulates angiogenesis in the developing and adult CNS through its membrane-bound receptors VEGFR-1(Flt1) and VEGFR-2 (Kdr)³⁰. In the early postnatal CNS, VEGFR-1 and 2 are highly expressed in the vascular ECs. However, the ligand VEGFA is barely detectable in the vascular ECs but highly expressed in the parenchymal neural cells

including oligodendroglial lineage cells^{20,36–38}. The previous study suggested that the HIF α -VEGF connection did not occur in the CNS oligodendroglia⁹ although this connection was demonstrated in the retina³⁹. In this study, we found that oligodendroglial HIF α cKO reduces VEGFA whereas oligodendroglial HIF α stabilization increases VEGFA expression, indicating that HIF α transcriptionally regulates VEGFA in oligodendroglial lineage cells. Further corroborating these findings, purified primary OPCs respond to HIF α signaling stabilizer (DMOG) and blocker (Chetomin) by activating and inactivating VEGFA, respectively. Our results are consistent with previous data showing

that VEGFA is a direct transcriptional target of HIFα^{40–42}. By leveraging our unique *in vivo* genetic models of VHL/VEGFA double cKO, we unequivocally prove that VEGFA is an essential downstream molecule that couples oligodendroglial HIFα function and vascular angiogenesis in the CNS, which is different from Yuen et al.⁹, who reported that VEGFA was unchanged in the CNS of oligodendroglial HIFα-stabilized mutants. The discrepancy may presumably reflect the intrinsic differences of *in vitro* pharmacological interventions and *in vivo* genetic manipulations.

It has been suggested that Wnt signaling regulates VEGF, or vice versa, to control angiogenesis^{43–45}. It is possible that

Wnt/β-catenin signaling is required for, or synergistically regulates, HIFα-activated VEGFA expression. Our data do not support this possibility. First, stabilizing oligodendroglial HIFα activates VEGFA but not Wnt/β-catenin signaling. Second, VEGF expression is indistinguishable in the CNS of oligodendroglial VHL/WLS double cKO mutants from that of oligodendroglial VHL single cKO mutants (data not shown), indicating that oligodendroglial-derived Wnt signaling plays a minor role in VEGFA expression. Third, Wnt/β-catenin activity is comparable in the CNS of oligodendroglial VHL/VEGFA double cKO mutants and VHL single cKO mutants, implying that oligodendroglia-derived VEGFA has no regulatory role in

Fig. 8 Astroglial HIF α stabilization promotes CNS angiogenesis and enhances Wnt signaling activity. **a** Fate-mapping study showing that mGfap-Cre-mediated EYFP was expressed in GFAP⁺ astrocytes but not in Sox10⁺ oligodendroglial lineage cells or NeuN⁺ neurons in the spinal cord at P60. Wnt/ β -catenin activity. Together, our results do not support a major interplay between oligodendroglial HIF α -activated VEGFA and Wnt/ β -catenin signaling in modulating CNS angiogenesis.

Previous studies including those from our own laboratory^{10,12,46–49} have shown that dysregulated Wnt/ β -catenin activity invariably inhibits oligodendrocyte differentiation and myelination. Given the normal level of Wnt/ β -catenin activity in the CNS of oligodendroglial HIF α -stabilized mutants, our study will spark renewed interests in studying Wnt-independent mechanisms underlying the impairment of oligodendroglial differentiation and myelination in HIF α -stabilized mutants as previously reported⁹. Interestingly, HIF α is stabilized and enriched in oligodendroglia in the active demyelinating lesions and normal-appearing white matter (NAWM) of multiple sclerosis patient brains^{50–53}. We show that HIF α stabilization in oligodendrocytes remarkably activates the angiogenic and neurotrophic factor VEGF in the CNS. The genetic models generated in our study also provide a powerful tool in determining the role of HIF α stabilization in OPCs and oligodendrocytes in the pathophysiology of demyelination and remyelination in multiple sclerosis and other neurological disorders in which hypoxia-like tissue injury occurs.

Methods

Animals. A total of 14 transgenic strains were used in this study. Cnp-Cre mice (RRID: MGI_3051754)¹¹, Sox10-Cre (RRID: IMSR_JAX:025807), Sox10-CreERT2 (RRID: IMSR_JAX: 027651), Pdgfra-CreERT2 (RRID: IMSR_JAX:018280), Aldh1l1-CreERT2 (RRID: IMSR_JAX:029655), Plp-CreERT2 (RRID: IMSR_JAX:005975), mGfap-Cre (RRID: IMSR_JAX:024098), Hif1 α -floxed (RRID: IMSR_JAX:007561), Hif2 α -floxed (RRID: IMSR_JAX:008407), Vhl-floxed (RRID: IMSR_JAX:012933), Wls-floxed (RRID: IMSR_JAX:012888), Vegfa-floxed (MGI:1931048)⁵⁴, Bat-lacZ (RRID: IMSR_JAX:005317), Rosa26-EYFP (RRID: IMSR_JAX:006148). Animals were housed at 12h light/dark cycle with free access to food and drink, and both males and females were used in this study. The single transgenic mice were crossed to generate double or triple transgenic mice indicated in the study. All Cre transgene was maintained as heterozygous. All transgenic mice were maintained on a C57BL/6 background. Animal protocols were approved by Institutional Animal Care and Use Committee at the University of California, Davis.

Primers used for genotyping Hif1 α -floxed, Hif2 α -floxed, and Vhl-floxed and for detecting Cre-mediated DNA deletion (as in Figs. 1a and 2a, b) were derived from previous study⁵⁵ and listed here. Hif1 α -F1: 5'-TTGGGGATGAAACATCTGC-3', Hif1 α -F2: 5'-GCAGTTAAGAGCACTAGTTG-3', Hif1 α -R: 5'-GGAGCTATCTCTAGACC-3', Hif2 α -F1: 5'-CAGGCAGTATGCCTGGCTAATTCCAGTT-3', Hif2 α -F2: 5'-CTTCTTCCATCATCTGGGACT-3', Hif2 α -R: 5'-GCTAACACTGTACTGTCTGAAAGAGTAGC-3', Vhl-F1: 5'-CTGGTACCCACGAACTGTC-3', Vhl-F2: 5'-CTAGGCACCGAGCTTAGAGGTTTGC-3' Vhl-R: 5'-CTGACTTCCACTGATGCTGTACAG-3'. Primers used for genotyping Wls-floxed for detecting Cre-mediated DNA deletion (as in Fig. 7b) were derived from previous study¹⁸ and listed here. Wls-F1: 5'-CTTCCCTGCTTCTTAAGC GTC-3', Wls-F2: 5'-AGGCTTCGAACGTAACAGGACC-3', Wls-R: 5'-CTCAGAAC TCCCTTCTGAAGC-3'.

Tamoxifen and BrdU (or EdU) treatment. Tamoxifen (TM) (T5648, Sigma) was dissolved in mixture of ethanol and sunflower oil (1:9 by volume) at a concentration of 30 mg/ml¹⁴. Mice were administered intraperitoneally (i.p.) with tamoxifen at dose of 200 μ g/g body weight at time points indicated in each figure. BrdU (B5002, Sigma) or EdU (A10044, Thermo Fisher Scientific) was freshly dissolved in 0.9% sterile saline at a concentration of 10 mg/ml. BrdU or EdU was i.p. injected to animals at a dose of 100 μ g/g body weight at time-points indicated in the figures. Tamoxifen was administered to both the controls and the inducible floxed mice in all experiments involving inducible Cre-LoxP approach.

Primary OPC culture. Primary mixed glial culture (MG) was prepared from the forebrains of neonatal pups between ages P0 and P2. The isolated cortical tissues were dissociated by papain dissociation kit (#LK003176, Worthington) supplemented with DNase I (250 U/ml; #D5025, Sigma) and D-(+)-glucose (0.36%; #0188 AMRESCO) in 33 °C/10% CO₂ for 90 min. Next, the tissues were transferred in PDS Kit-Inhibitor solution (#LK003182, Worthington). Tissue chunks were triturated, and then collect the cell suspension supernatant. After centrifugation, cells were plated on poly-D-lysine (PDL, #A003-E, Millipore)-coated 10 cm dishes (#130182, Thermo Scientific) in high-glucose DMEM medium (#1196092, Thermo Fisher) with 10% heat-inactivated fetal bovine serum (#12306-C, Sigma) and penicillin/streptomycin (P/S, #15140122, Thermo Fisher). After 24 h, attached cells were washed with HBSS (#24020117, Thermo Fisher) to remove serum, and maintained with serum-free growth medium (GM), a 3:7 mixture (v/v) of B104 neuroblastoma-conditioned medium, 10 ng/ml Biotin (#B4639, Sigma), and N1 medium (high-glucose DMEM supplemented with 5 μ g/ml insulin (#16634, Sigma), 50 μ g/ml apo-transferrin (#T2036, Sigma), 100 μ M Putrescine (#P5780, Sigma), 30 nM Sodium selenite (#S5261, Sigma), 20 nM Progesterone (#P0130, Sigma). We performed immunopanning 96 h after GM maintenance. Before immunopanning, cells were resuspended in panning solution (0.1% BSA in N1 medium). The cells were panned once with the anti-Thy1.2 antibody (#105302, Biolegend) for negative immunopanning and then panned once with the anti-NG2 antibody (#AB5320, Millipore) for positive immunopanning. OPCs were cultured on PDL-coated plates with complete GM. The complete GM consisted of GM with 5 ng/ml FGF (#450-33, Peprotech), 4 ng/ml PDGF-AA (#315-17, Peprotech), 50 μ M Forskolin (#6652995, Peprotech), and glutamax (#35050, Thermo Fisher). To induce differentiation, the medium was switched to differentiation medium (DM), which consists of 12.5 μ g/ml insulin, 100 μ M Putrescine, 24 nM Sodium selenite, 10 nM Progesterone, 10 ng/ml Biotin, 50 μ g/ml Transferrin (#T8158, Sigma), 30 ng/ml 3,3',5'-Triiodo-L-thyronine (#T5516, Sigma), 40 ng/ml L-Thyroxine (#T0397, Sigma-Aldrich), glutamax and P/S in F12/high-glucose DMEM, 1:1 in medium (#11330032, Thermo Fisher Scientific).

HIF α signaling stabilization and inhibition in vitro. Purified brain primary OPCs were pre-incubated with 100 nM Chetomin or DMSO control for 2 h, and then switched to the fresh culture medium with 1 mM Dimethylxalylglycine (DMOG, D3695, Sigma) in the presence of 100 nM Chetomin (C9623, Sigma) or DMSO (D8418, Sigma) control for 7 h before RNA preparation.

VEGFA ELISA assay. Cell culture medium of primary OPCs from Non-Cre control and Cnp-Cre, Hif1 α ^{f/f}, Hif2 α ^{f/f} were collected for VEGF measurement. Endogenous VEGF concentrations were determined using a mouse-specific VEGF Quantikine ELISA kit (t#MMV00, R&D System) according to the manufacture's instruction.

Transfection in primary OPCs and ELISA assay. Primary OPCs was transfected with Wls-ShRNA (TRCN 0000 234932, Mission ShRNA bacterial glycerol stock

NM_026582) and ShRNA scramble control (Mission TRC2 Plk0.5-PURO Non-Mammalian shRNA control Plasmid), Wnt7a plasmid pLCN-Wnt7a-HA (Addgene, #18036) and empty pLCN-exp (Addgene, #64865) at the time points indicated in Fig. 3a. The transfection was done by using FuGENE6 Transfection reagent (Promega, #E2691, lot#000371257). The Wnt7a in OPCs cell medium was measured by using mouse Wnt7a ELISA kit (Cusabio, #CSB-EL026141MO, Lot#G19147708) according to the manual of the kit.

Immunohistochemistry and blood vessel quantification. Study mice were perfused with ice-cold phosphate buffered saline (PBS, pH = 7.0, Catalog #BP399-20, Fisher Chemical), and then post-fix in fresh 4% paraformaldehyde (PFA, Catalog #1570-S, Electron Microscopy Science, PA) at room temperature (RT) for 2 h. The CNS tissue was washed in ice-cold PBS for three times, 15 min each time. The samples were cryoprotected with 30% sucrose in PBS (Sucrose, Catalog #S5-3, Fisher Chemical) for 20 h followed by sectioning. Sixteen microns thick sections were serially collected and stored in -80°C . Immunohistochemistry was conducted as below: slices were air dry in RT for at least 1 h, and then were blocked

with 10% Donkey (Dky) serum for 1 h at RT. Tissue was incubated with primary antibody overnight at 4°C . Slices were washed for 15 min in PBST (PBS with 0.1% Tween-20) for three times, then incubated with fluorescence conjugated secondary antibody (1:500; Alexa-fluorescence from Jackson ImmunoResearch) for 1.5 h at RT. Slices were washed 15 min in PBST (PBS with 0.1% Tween-20) for three times. The immunostaining was done before incubating with DAPI nuclear staining for 10 min^{56,57}. The information of primary antibodies used for immunohistochemistry in the study were listed in Supplementary Table 1. For BrdU immunostaining, sections were pretreated with fresh-made 2N HCl (#320331, Sigma) followed by the above immunostaining procedures.

To quantify blood vessel density, we used projected confocal images at 40x magnification (Nikon C1) followed by NIH ImageJ automated processing. At least three sections from each mouse were used for ImageJ quantification. Ten-micron-thick optical sections from confocal z-stack images were projected into a flattened image. The parameter setting of z-stack confocal imaging is below: total optical thickness, 10 μ m, step size, 0.5 μ m, total number optical slices, 21. The volume-rendered confocal images were subsequently imported to NIH ImageJ 1.46r for quantifying Laminin-positive blood vessel density using a customer-defined Macro

program. The total area and Laminin-occupying area were derived and from ImageJ and exported to Microsoft Excel for calculating the percent of Laminin-occupying area among assessed total CNS area.

mRNA In Situ hybridization (ISH). We employed the PCR and in vitro transcription to prepare cRNA probes targeting *Vegfa* and *Plp*⁵⁸. Targeted sequences of *Vegfa* and *Plp* were generated by PCR. The primers used were: *Vegfa*-Forward: GGATATGTTTGAAGCTGCTGTGGA; *Vegfa*-Reverse: AGGGAAGATGAGGAA GGGTAAG; *Plp*-Forward: GGGGATGCCTGAGAAGGT; *Plp*-Reverse: TGTGA TGCTTTCTGCCCCA. We added the T7 (GCGTAATACGACTCACTATAGGG) and SP6 (GCGATTTAGGTGACACTATAG) promoter sequences to the 5' of the forward and reverse primers, respectively. The SP6 and T7 promoter sequences are recognized by the SP6 and T7 RNA polymerase, respectively, in the subsequence in vitro transcription. PCR products of *Vegfa* and *Plp* amplification were used as DNA templates to transcribe into *Vegfa* and *Plp* cRNA probes in vitro using SP6 RNA polymerase. T7 RNA polymerase-mediated transcription of RNA was used as negative control. DIG-UTP or FITC-UTP was used to generate DIG- or FITC-labeled cRNA probes.

Single or dual mRNA ISH was done using our previous protocols⁵⁸. Frozen sections of 14 μm thickness were used. The concentration of cRNA probe we used was 100 ng/100 μl hybridization buffer. Hybridization was conducted at 65 $^{\circ}\text{C}$ for 18–20 h. After hybridization, sections were treated with 10 $\mu\text{g}/\text{ml}$ RNase A to eliminate nonspecific cRNA binding. For single mRNA ISH with DIG-labeled cRNA probes, DIG was recognized by alkaline phosphatase (AP)-conjugated anti-DIG (#11093274910, Sigma) antibody and DIG signals were visualized by the NBT/BCIP (#72091, Sigma) method. For dual fluorescence mRNA ISH (*Vegfa* and *Plp*), FITC-labeled *Plp* cRNA probe and DIG-labeled *Vegfa* cRNA probe were applied to frozen sections simultaneously during the hybridization step. The FITC signals

were visualized by tyramide signal amplification (TSA) fluorescence system (#NEL747A, Perkin Elmer) according to the manufacturer's instructions using horseradish peroxidase (HRP)-IgG Fraction Monoclonal Mouse Anti-Fluorescein (#200-032-037, Jackson ImmunoResearch). DIG signals were visualized by a HNPP fluorescent kit (#11758888001, Sigma) according to the manufacturer's instructions using AP-conjugated anti-DIG Fab² antibody (#11093274910, Sigma).

Western blot. Protein concentration was assessed by BCA protein assay kit (#23225, Thermo Fisher Scientific). Twenty microgram protein lysates were separated on AnyKD Mini-PROTEAN TGX precast gels (#4569035, BIO-RAD) or 10% Mini-PROTEAN TGX precast gels (#4561035, BIO-RAD). The proteins were transferred onto 0.2 μm nitrocellulose membrane (#1704158, BIO-RAD) by Trans-Blot Turbo Transfer system (#1704150, BIO-RAD). The membranes were blocked with 5% BSA (#9998, Cell signaling) for 1 h at room temperature and were incubated overnight with primary antibodies (Supplementary Table 2) at 4 $^{\circ}\text{C}$. The membranes were washed 3 times with 10 mM Tris-HCl (pH 7.5) containing 150 mM NaCl and 0.1% Tween-20 (TBST) and were incubated with horseradish peroxidase-conjugated goat anti-rabbit (31460, RRID: AB_228341, Thermo Fisher Scientific) or anti-mouse (31430, RRID: AB_228307, Thermo Fisher Scientific) for 1 h at room temperature. After incubation, the membranes were washed three times with TBST. Specific binding was detected using Western Lightening Plus ECL (NEL103001EA, Perkin Elmer). NIH Image J 1.44p was used to quantify protein expression levels by analyzing the scanned grey-scale films.

RNA preparation and RT-qPCR. Total RNA was extracted by using Qiagen RNeasy for lipid tissues (74804, Qiagen) with additional on-column DNase I digestion to remove genomic DNA contamination. The quality and quantity of

RNAs were analyzed by the Nanodrop one^C microvolume UV-Vis Spectrophotometer (ND-ONEC-W, Thermo Fisher Scientific). cDNA was synthesized by Qiagen Omniscript RT Kit (205111, Qiagen). The relative mRNA level of indicated genes was normalized to that of the internal control Hsp90 and calculated by the equation $2^{-\Delta(\text{Ct}(\text{cycle threshold of Hsp90} - \text{Ct of indicated genes}))}$. The gene expression levels in control groups were normalized to 1. RT-qPCR was conducted by QuantiTect SYBR[®] Green PCR Kit (204145, QIAGEN) approaches on Agilent MP3005P thermocycler. The qPCR primers used in the study were listed in Supplementary Table 3.

Statistical analyses. Quantification was performed by blinded observers. All measurements were taken from distinct mice and quantitative data are presented as means \pm standard deviation (s.d.). We used scatter dot plots to present the quantification data throughout our manuscript. Each dot (circle, square, or triangle) in the scatter dot plots represents one mouse or one independent experiment. Shapiro–Wilk approach was used for testing data normality. F test was used to compare the equality of variances of two groups whereas Browne–Forsythe test was used for comparing the equality of variances of three or more groups. The statistical methods were described in the figure legends and P value was presented in each graph. For unpaired, two-tailed Student's *t* test, *t* value and degree of freedom (df) were presented as $t_{(df)}$ in figure legends. Welch's correction was used for Student's *t* test if the variances of two groups were unequal after Browne–Forsythe test. For comparisons among three or more groups with equal variances (tested by Browne–Forsythe approach), ordinary one-way ANOVA was used followed by Tukey's multiple comparisons, otherwise Welch's ANOVA was used followed by unpaired *t* test with Welch's correction. In ordinary ANOVA, the F ratio and DFn and Dfd was presented as $F_{(DFn, Dfd)}$ in the figure legends where DFn stands for degree of freedom numerator and Dfd for degree of freedom of denominator. In Welch's ANOVA, the Welch's F ratio, W and DFn and Dfd was presented as $W_{(DFn, Dfd)}$ in the figure legends. All data plotting and statistical analyses were performed using GraphPad Prism version 8.0. P value less than 0.05 was considered as significant, whereas greater than 0.05 was assigned as not significant (ns).

Reporting summary. Further information on research design is available in the Nature Research Reporting Summary linked to this article.

Acknowledgements

This study was supported by the grants funded by NIH/NINDS (R21NS109790, R01NS094559, and R21NS093559 to F.G.) and Shriners Hospitals for Children (86100, 85200-NCA16, 85107-NCA-19 to F.G., 84307-NCAL to S.Z.).

Author contributions

F.G. conceived the original idea, led the project, and wrote the paper. S.Z. and B.K. conceived the idea, designed and performed experiments, analyzed data, and wrote the paper. X.Z., X.G., Y.W., Z.L., P.P., K.F., and A.W. analyzed data and edit the paper. All the authors provided feedback and comments on the paper.

Competing interests

The authors declare no competing interests.

Additional information

Supplementary information is available for this paper at <https://doi.org/10.1038/s41467-020-15656-4>.

Correspondence and requests for materials should be addressed to F.G.

Peer review information *Nature Communications* thanks Robert Miller, and the other, anonymous, reviewer(s) for their contribution to the peer review of this work. Peer reviewer reports are available.
